THE AREA

The Buffalo Lake Moraine Conservation Area is made up of 6 contiguous quarters of land, located 18 km north of Stettler, in south-central Alberta. Known originally as the Caine property, the quarters were variously purchased by The Alberta Conservation Association, The Alberta Fish and Game Association, Ducks Unlimited Canada and The Nature Conservancy of Canada in June 1999. Additional quarters have been purchased since then.

Ecologically, the area is made up of rolling, morainal aspen parkland. There is evidence that some areas were cultivated well over 50 years ago, but since that time, the land has been used for grazing cattle. A grazing inventory study was carried out by Mancroft-EBA Consultants Ltd. (1998). A detailed vegetation and range resource inventory was carried out in 2005 (Rangeland Conservation Service Limited, 2006). No grazing was allowed in 1999. In 2000 the area was divided into 3 grazing paddocks.

Since 2000 limited grazing has been allowed with one of the quarters/paddocks being idled each year.

BACKGROUND

Provincial Parks and other areas where natural vegetation is protected are of great value as the flora and fauna present in them is typical of what was in Alberta before widespread agricultural activities replaced them with flora and fauna that was reduced in numbers and made up of species that were associated with cultivated grains and hay crops. As a result, many of Alberta's "rare and endangered" species are now found only, or mainly, in such protected areas.

The writer, now retired and living in Erskine, Alberta, has long been interested in the natural flora and fauna of the province. He is a member of the Alberta Lepidopterist's Guild, the purpose of which is to encourage study of Alberta's moths and butterflies. In the spring of 2000, he commenced an examination of the moths of south-central Alberta, the purpose of which was to document the species present in various natural areas. He became acquainted with The Buffalo Lake Conservation Area in 1999, when it was still in private hands. This led to the procurement, with help from Grant Nieman, of a Letter

of Authority to collect in the Area in 2001, the purpose of which was to produce the present baseline list. The Area was visited sixteen times during the year: April 1, 15, 25 and 28; May 7, 15 and 31; June 22; July 5 and 15; August 4, 22 and 30; and September 12, 17 and 24 (Bird 2002). Ernest Mengersen collected with the author on the night of April 28/29. The first two visits to the area were mainly for reconnaissance and two areas were selected for light trapping, one being an open, grassland/silver willow area, the other being on a trail through aspen woods. On all subsequent visits, one trap was set up in each of these two habitats. On all but the first two visits, two ultraviolet light traps were run overnight. No attempts were made to capture specimens with a mercury vapor light and sheet, by sugaring, or, other than the first two visits, search for diurnal species. The area was visited 6 additional times in 2002: May 10, 19 and 29; June 23, August 17 and September 9, with UV light traps being set up each night (Bird 2003). On August 17, the writer was accompanied by Gary Anweiler, Felix Sperling and Doug Macaulay and a mercury vapor light and sheet were also set up that night. Research in the area was carried out 8 times in 2003: May 29; June 12 and 29; July 10, 20 and 27; and August 8 and 30. UV traps were set out four times in 2004: June 4 and 18, July 25 and August 30. In 2005, collecting was carried out on the nights of May 20 and 26 and on June 19. In 2006, sampling was done on the nights of May 13 and 24, June 24, July 13, and August 3 and 16.

There is still much to be learned about the distribution and status of lepidopteran (moth and butterfly) species in south-central Alberta. Baseline studies of this sort provide information that helps characterize the species associated with various ecoregions, in the present case Aspen Parkland; determine the status designations (abundant, common, rare, endangered) of various species; show the effects of grazing on species composition and abundance; and allow the examination of many other parameters, including phenology, dry vs. wet years, and outbreaks of various species such as forest tent caterpillar.

SPECIMEN DISPOSITION

All specimens collected by the writer presently reside in his collection but they will eventually be donated to the Strickland Museum at the University of Alberta, to the Northern Forest Research Centre, and possibly also to the Canadian National Collection.

CHECKLIST

The order, and terminology, is that of R.W. Hodges (1983) except where recent changes in taxonomy have occurred. Except for a few made by Ernest Mengersen and Gary Anweiler, all collections were made by the writer. While most of the larger or

macromoths are relatively well known, the same cannot be said for some of the smaller or micromoths. Identifications, especially of the latter, can be difficult or are at present impossible, until such time as revisionary studies are made. This is especially true in the family Gelechiidae. Also, genitalic dissection and examination is necessary for positive identification in some groups. For these reasons, some of the determinations should be regarded as tentative. The scientific names of the species are followed by the date-month-year of the collection and the number of individuals mounted; EM indicates a collection made by Ernest Mengersen; and an “SR” indicates a sight record. Common names are added if such are known to exist.

Kenneth Bowman’s (1951) list of the Lepidoptera of Alberta presents all species known at that time and gives the distribution of each according to 21 Areas. His areas 5, 8 and 10 essentially cover all of south-central Alberta, with the study area being in Area 8. Most of Bowman’s records are from Area 10, which includes Edmonton, so most of the species found in the following list would be additions to his Area 8.

The present report incorporates all of the findings in the previous reports (Bird 2001-2006), and includes a number of corrections to previous identifications.

The forewings lack the AM and PM lines usually associated with *A. ruricolella*. Some specimens have the ST lines usually associated with *A. plumbifimbriella*, though this line, if present, is faint. Most fresh specimens have a distinct yellowish-orange shade in the terminal area in which the seven black dots are found. *Agriphila ruricolella* lacks this feature. *Agriphila ruricolella* is basically an eastern species while *A. plumbifimbriella* is western. There are no known genitalic differences between the two species. Thus, taking everything into account, this material fits *plumbifimbriella* better than *ruricolella*. It is also possible that *plumbifimbriella* should be regarded as a synonym of *ruricolella*.

DISCUSSION

A meaningful comparison can be made between this area and that of a parallel study made on the smaller Hall acreage, 3 km south of Nevis, as both are excellent examples of Aspen Parkland. Percentage-wise, 62.2% (352 species) of the recorded moths were common to both, while 25.9% (147 species) were found only in the present, larger area and 12% (68 species) were found only in the smaller Hall acreage study. As both areas are very similar, it is highly likely that, if further study were carried out, the percentage of species common to both would go up. On the other hand, and because the present study area is larger and somewhat more ecologically diverse, it will always have more species. This points out the need, when setting aside areas for protection such as Parks, Ecological Areas and Conservation Areas, that they be of sufficient size so that they provide protection for a larger number of species. Though the present study deals primarily with moths, the same reasoning obviously applies to other faunistic groups, as well as to all floristic groups.

A comparison can also be made between the moths of the Buffalo Lake Conservation Area and those of Dry Island Buffalo Jump Provincial Park. Percentage-wise, 49.6% (342 species) of the recorded moths were common to both, while 27.9% (194 species) were found only in the Buffalo Lake area and 22.9% (159 species) were found only in the Dry Island area. This can be explained on the basis of the ecological dissimilarities of the two areas: the Buffalo Lake area being typical native Aspen Parkland; while the Dry Island area is comprised of diverse communities, including riverine forest, badland terrain on south facing slopes, native grassland, shrubland and mixed woods on north-facing slopes. The higher number of plant species and the greater range of soil and microclimate habitats in the Dry Island area meet the ecological requirements of a greater number of moth species.

SUMMARY

A steadily increasing number of species have become known for the area as research progressed: 304 in 2001 (Bird 2002), 374 in 2002 (Bird 2003), 400 in 2003 (Bird 2004), 434 in 2004 (Bird 2005), 464 in 2005 (Bird 2006), while the present report based on 2006 research, lists 532 species. While this may seem an impressive number, it is felt that, with further study, this total could be brought up to over 600. To put things into perspective, it is known that there are over 1000 macromoths and 1000 micromoths in the province. The present report is still “a work in progress”. More species can still be added, a few of the present reports may be found to be based on misidentifications, and there are many species in the “unknown” category, especially in the Gelechiidae and other micromoth groups, which will eventually be determined or described.

It was interesting that another specimen of *Oncocnemis saundersiana* was found in 2002. This species, found in the area in 2001, has still not been collected anywhere else in Alberta. A specimen of *Scythris mixaula* was collected in 2003 and it was a second record for Alberta and also for Canada. *Pyrausta scurrallis*, which has been collected twice in the area, is another new species for Alberta. The collection in 2005 of a specimen of *Acanthopteroctetes bimaculata*, also a second report for Alberta, is further evidence that other interesting findings remain to be made.

Moths were found on all visits but peak numbers occurred during the summer months. As most species were encountered over a 1-2 week period, attempts were made to sample frequently. Weather and other conditions sometimes prevented sampling.

ACKNOWLEDGEMENTS

Grant Nieman and Andy Murphy, of the Alberta Conservation Association, are thanked for issuing Letters of Authority to allow the collecting of Lepidoptera in the Buffalo Lake Conservation Area in order to arrive at the putting together of a baseline list of the species of the area, and also for supplying a key to allow vehicle access when transporting traps into and out of the Area. Thanks are also extended to Bob Thompson of Ducks Unlimited for assisting with access and also for providing encouragement. Sincere thanks are extended to Gary Anweiler for his help in naming or verifying the macromoths, and Greg Pohl for his assistance in the identification of micromoths. Chris Schmidt verified the Arctiids and some of the Geometrids. Also to be thanked are Dr. J.-F. Landry for help with *Coleophora* and *Scythris*, Doug Macaulay for identifying Pterophorids and Dr. George Balogh for identifying specimens of the genus *Eupithecia*. Even though, others helped, I personally take responsibility for the identification of the species mentioned in this report.

The Alberta Conservation Association deserves special thanks for providing a \$1000 grant in 2006 which allowed the purchase of an additional UV moth trap, 3 batteries, ethyl acetate and insect pins. Felix Sperling and Danny Shpeley facilitated the study of specimens in the Bowman Collection of the Strickland Museum, and Greg Pohl did the same for the Northern Forest Research Centre Entomology Collection. Ernest Mengersen is thanked for identifying several species and for allowing access to the Entomology Collection at Olds College.
